Abstract

With the sudden growth of cryptocurrency, the researchers decided to conduct this study that can help further understand cryptocurrency through different variables of understanding and analysis that can help determine the underlying growth and importance of cryptocurrency. Throughout the study, the researchers have gathered information to understand cryptocurrency, such as its definition, origin, and purpose. To address the problem, by answering the questions that linger in people's minds about the functions, benefits, security, and diverse uses of cryptocurrency, the researchers solidified its credibility and viability as an investment vehicle. Regression analysis and time-series models were implemented through statistical data analysis, data collection, and forecasting of contextual data. Then, after getting the forecasting contextual data, the researchers compared the historical time series data and the forecast data to analyze and evaluate it. The findings confirm the influence of cryptocurrency on inflation, the similarities and differences between the historical price data and forecast data, and the visualization result of the forecasting with the given data. The research shows a clear understanding of how cryptocurrency works by providing information, gathering data for it to be analyzed and evaluated, and visualizing the data through forecasting as it can be considered a prominent study by both researchers and investors due to its important role in the economy. The study aimed to understand cryptocurrency by analyzing the behavior and movement of the market in order to achieve the best profit margins for investing while avoiding investment risk.

INTRODUCTION

Background of the Study

There are many different types of currency emerging in our economy today, including cryptocurrency, fiat currency, and digital currency. They are used as a platform for buying, trading, and selling. Cryptocurrency is a digital or virtual currency that is protected by cryptography, making counterfeiting or double-spending nearly impossible (Frankenfield, 2022b). Many cryptocurrencies use blockchain technology to create decentralized networks. A diverse network of computers enforces a distributed ledger. Many companies in this research study have created their own currencies, known as tokens, which can be exchanged for the goods or services that the company provides. Think of them as arcade tokens or casino chips. You must first exchange real currency for cryptocurrency in order to gain access to the good or service.

A fiat currency or money, on the other hand, is a government-issued currency that is not backed by a physical commodity such as gold or silver, but rather by the government that issued it. According to Chen (2022), the value of fiat money is determined by the relationship between supply and demand as well as the stability of the issuing government, rather than the value of a commodity backing it, as is the case with commodity money. The majority of modern paper currencies, including the US dollar, euro, and other major global currencies, are fiat currencies. Furthermore, digital currency refers to any form of payment that is solely electronic. Digital money, unlike a dollar bill or a coin, is not physically tangible. Computers are used to account for and transfer it. The cryptocurrency Bitcoin is a well-known form of digital money. In this case, digital currency can be a fiat currency such as dollars or euros, as well as digital money. To exchange digital money, smartphones, credit cards, and online cryptocurrency exchanges are all used. In some cases, it can be converted into physical cash, such as by withdrawing cash from an ATM. Speculation fuels the cryptocurrency market. To profit, investors bet on whether prices would rise or fall. These speculative bets result in a sudden influx of money or a sudden outflow of money, resulting in high volatility. The media and availability can also contribute to cryptocurrency fluctuations. Bitcoin's price rises as more institutions use it as an investment and medium of exchange. Furthermore, many people have lost faith in their fiat currency and are looking for alternative ways to store their money (NDTV Business Desk, 2021b).

Digital currency is the electronic form of fiat money issued by governments, whereas cryptocurrency is a secure store of value (NDTV Business Desk, 2021a). Modern currencies (including cryptocurrencies) are all digital or electronic in nature. Money is deposited and withdrawn from your bank account electronically. 90% of the world's money is kept electronically. For decades, we have been using digital currencies. What uninformed people call "digital" currency is simply a shift from 90% to 100% digital, that is, the abolition of paper money and checks, as well as all of the financial infrastructure required to support them. These currencies play an important role in our economy. It has many advantages that will benefit us (Frankenfield, 2022a). Furthermore, you can store your funds in one of two wallets, each of which can be quickly converted to your account. In addition, there are no fees for storing digital currencies in wallets. Most people value their anonymity. Payments in digital currencies, on the other hand, are made directly between the executing parties without the need for any go-betweens, so the exchanges are typically brief and require a lower cost. These fees are more reasonable when compared to traditional payment methods such as banks. One of the advantages of cryptocurrency is that it does not require a bank account (Khanna, 2012). Despite the fast growth in popularity and usage of cryptocurrency and digital currency, there are still questions that are asked by newcomers or people that are confused by the system. Whether it is due to uncertainty, unawareness, or reassurance, these digital assets are so vulnerable that a single mistake can make everything go to waste. Assurance is the best thing to do when it comes to going to uncharted territories, especially when what you are handling are important assets that can be vital or beneficial to you.

Despite the uncertainty about whether cryptocurrency is safe or not, cryptocurrency is safe because of blockchain. Blockchain is the technology that enables cryptocurrencies to work. It is a decentralized digital ledger of transactions used for cryptocurrencies and other assets and functions. It is important to separate the technology behind cryptocurrencies from actual cryptocurrencies. There is a digital validation process to verify each transaction added to the blockchain and prevent fraud. While some cryptocurrencies are legitimate, there is also the potential for fraud and theft. On top of that, because cryptocurrency is so trendy, there are investment schemes surrounding these currencies. It is bad enough that the Securities and Exchange Commission issued an investor alert about fraud surrounding cryptocurrency. If you are an investor, then it should be plausible since investment is all about risk. The probability of profiting is high, but it is also the same, or worse, higher when it comes to losing.

Literature Review

An Introduction to Cryptocurrency

Studies about cryptocurrency started on December 27, 2018, when Zura Kakushadze and Ronald P. Russo studied BlockChain, where they conducted research to educate investors on the legitimate use of BlockChain since its popularity for using cryptocurrency and digital currency has been rising ever since. The researchers surveyed how blockchain works, how it is used currently, and some ideas for its expansion and concluded that direct-payment services do not expose users to illiquidity and exchange rate risk, meaning there is no need for anonymity (Kakushadze & Russo, 2018). Chiu & Koepl (2019) studied Blockchain-Based Settlement for Asset Trading, where the research was made to analyze the effectiveness of using BlockChain Technology when engaging in a blockchain-based settlement and revealed that the advantages of blockchain-based settlement can be maximized when the transaction number is large, default risk is low, and the number of miners is large.

Even after three years, researchers continue to have questions about cryptocurrency. The most recent developments are the Trading and Arbitrage in Cryptocurrency Markets, in which researchers attempt to capture the quantum of "arbitrage profit" and conclude that the price pressure of net orders is mostly permanent at the daily level, with a 4% return for purchasing 10,000 bitcoins. However, the component of the signed volume of net order flow that is common across exchanges explains approximately 50% of the returns at the five-minute and hourly levels, and nearly 85% at the daily level (Makarov & Schoar, 2020). According to Chuen et al. (2018), the price of Bitcoin does not fluctuate in the same direction as the stock market. This low historical correlation with traditional asset classes such as stocks, bonds, and cash suggests the possibility of an alternative asset class that could act as a source of diversification for traditional assets.

In this case, this research would be studying cryptocurrency using the Theory of Stock Market Efficiency, which examines the attacks on the efficient market hypothesis and the relationship between predictability and efficiency, and concludes that it is not significant in the long run. In this view, the efficient market hypothesis remains valid (Malkiel, 2003). According to Matvos, Seru and Silva (2018), in periods of stressed financial markets, firms tend to diversify their operations in areas that have negative correlations with their current activities. They find that non-financial firms tend to diversify into operations with negative financial correlations during times of

stressed financial markets. Boudoukh et al. (2019) also analyzed firm-level public news if it is closely linked and relevant to the changes happening in the stock prices, and later demonstrated that firm-level public news can actually be a meaningful component of stock return variance.

Insights and Implications of the Study

The methodologies used in the aforementioned studies varied. Among them is the one used by Walther et al. (2019), who provided their own framework called the GARCH-mixed data sampling framework (GARCH-MIDAS) and demonstrated the efficacy of the GARCH-MIDAS framework, which uses prediction quality to identify key drivers of volatility in cryptocurrencies like bitcoin, Ethereum, Ripple, and Stellar. The framework divides volatility into short-term and long-term components and identifies global real economic activity as the primary driver of long-term cryptocurrency volatility, which is important for investors with longer investment horizons (Walther et al., 2020).

In addition, Tuarob et al. (2021) proposed the DAVIS Framework, a unified solution for data collection, analysis, and visualization in real-time stock market prediction, to retrieve and process relevant financial data from news articles, social media, and company technical information. The researchers' goal is to provide stock investors with not only useful information but also meaningful visualization that allows investors to effectively interpret storyline events affecting stock prices. According to Huang (2019), the researcher finds additional evidence of investors' greater propensity to purchase new stocks in an industry if they previously earned positive excess returns in that same industry, with a stronger effect for more recent experiences and for investors who are less sophisticated or diversified, and that it does not enhance wealth. The effect varies according to the time horizon, investor sophistication, and diversification.

Synthesis

All of these researches showed that when doing a transaction in a cryptocurrency or digital currency market you can rely on blockchain since it does protect the transactors when engaging in a transaction digitally, the Efficient Market Hypothesis proves that the market is in its true value, the market is absolute neither technical analysis and/or fundamental can be used for forecasting the market meaning it is impossible to beat the market, the price of Bitcoin does not fluctuate in the same direction as the stock market meaning there is a difference in cryptocurrency

and digital currency when it comes to the market and researchers have been proposing their own framework which can provide much clear and useful information for stock investors called DAViS Framework which is said to be a unified solution for data collection, analysis, and visualization in real-time stock market prediction.

All of the studies stated above were somewhat related or relevant to this study; but this study will focus on the difference between digital currency and cryptocurrency with similar data collection techniques and analysis techniques and comparing and analyzing if there really is a similarity and differences and piece together the possibility of any sign of co-existing between both currencies.

Theoretical and Conceptual Framework

The Theory of Stock Market Efficiency, also known as the Efficient Market Hypothesis (EMH), holds that the market is perfect and that profiting excessively from it is nearly impossible. In the 1960s, economist Eugene Fama's Ph.D. dissertation inspired the EMH. According to the theory of stock market efficiency, the price of an asset today is its true value, reflecting any data that could drive its price up or down. If the efficiency theory is correct, all of the work done by market analysts is for naught (Faris, 2019).

The Theory of Efficient Stock Markets and this study will be on opposing sides of the coin. According to the EMH, or Efficient Market Hypothesis, the market is absolute. It holds that when new information enters the market, stock prices immediately reflect it; neither technical analysis (the study of past stock prices in an attempt to predict future prices) nor fundamental analysis (the study of financial information) can assist an investor (Ball, 1995; 1996; Faris, 2019).

This research will be predictive or forecast, which means it will estimate historical data to predict the direction of future trends. Both the EMH and this research will provide evidence as to whether or not the other is correct. Because it has been stated that both technical and fundamental analysis are useless in the market, we will use both techniques to forecast the future stock market. Active investing techniques can be used to outperform the market. However, statistics show that only a small percentage of those who try succeed. Only about one-quarter of businesses outperform the market. That is why many researchers believe that EMH is valid, but there is a possibility, but not a good one.

Figure 1
Conceptual Framework of the Study

The research study employed an IPO model to determine the variable that is favorable to the study. The inputs are historical price information (HPI) and financial news information. The process was to analyze contextual data coming from different sources. On HPI, the researchers gathered the elements important for forecasting future stock prices, and on financial news information, the researchers gathered news and checked whether there would be an effect based on the news. The output was decided by the results of making predictions about future stock prices and talking about whether there is a link between the historical price data and the predictions.

Statement of the Purpose

This study aimed to understand the growth of cryptocurrency, the similarities and differences between them, and to evaluate their possible increase and influence in the economy. Furthermore, it aimed to accomplish the following as well:

1. Determine whether cryptocurrencies can resist inflation.
2. Evaluate factors that affect the relationship between historical price data and forecast data.
3. Analyze and understand cryptocurrency through the method of forecasting.

METHODOLOGY

Research Design

The correlational research design was used in this study, which aimed to identify and understand the similarities and differences between digital currency and cryptocurrency from heterogeneous sources; regression analysis; and time-series models were implemented through statistical data analysis, data collection, and forecasting of contextual data. Then, after getting the forecasting contextual data, the researchers compared the historical time series data and the forecast data to analyze and evaluate if the forecast data is proportional to the historical price data.

Sample and Sampling Technique

This study will employ time series analysis, which can be useful in determining how a specific asset or economic variable changes over time. It can also be used to compare the changes associated with the selected data point to changes in other variables over the same time period (Jose, 2021).

The Classical Multiplicative Time Series Model will be used by the researchers, with $Y_t = S_t \times I_t \times T_t$. Whereas the time series value, Y_t , is the original data; S_t , or seasonality component, is a time series characteristic characterized by regular and predictable changes—seasonal refers to any predictable fluctuation or pattern that recurs or repeats over a one-year period (Karra, 2020); I_t , or the irregular component, is what remains after estimating and removing the seasonal and trend components of a time series. It is caused by the series' short-term fluctuations, which are neither systematic nor predictable. It is a time code column, a time period for which the trend component will be obtained.

On the other hand, the moving average, or MA, is a statistic that measures the average change in a data series over time. It is also important to understand the direction of the Y_t price movement. Upward movement indicates a positive or increasing result, straight movement indicates a neutral result, and downward movement indicates a negative or decreasing result. This will determine which way the predicted result will go. You must compute the moving average if and only if the total set is an even number. CMA, or Center Moving Average, is when moving averages are placed in the middle of a range rather than at the end. This is done to place the moving average values at their most central points in time (Minitab, 2022). If the overall set is an odd number, you don't need a CMA because the MA is already the Center Moving Average. When CMA provides a point of comparison, it can be considered a baseline. It serves as a foundation for all other modeling techniques applied to your problem.

Deseasonalized data can be used to investigate the trend and any remaining irregular components. T_t , or trend component, depicts the data's general tendency to increase or decrease over time. A trend is a consistent, long-term, average tendency (Sethi, 2019). It is not always necessary for the increase or decrease to be in the same direction over a given time period.

Research Instrument

One type of contextual information will be investigated in this research study for its predictability in the movement of the cryptocurrency and digital currency

markets. Historical Price Information (HPI), Technical information can be used to perform mathematical calculations with a variety of variables. In this research, information on stock prices was collected by analyzing historical stock data from the coinmarketcap website using the application programming interface (API), with a focus on one attribute: Live Price Data (Tuarob et al., 2021).

The researchers used technical analysis to obtain HPI, which examines a security's price movement and uses this information to forecast future price movements. The study of price and volume is central to technical analysis. This data assists analysts in improving their overall valuation estimates (Udemy, Inc., 2022).

Data Gathering Procedure

The goal of all of this is to understand how prices move through time and then be able to project them into the future. Since the data is composed of only a month's worth of data, the researchers tried to forecast a month's worth of data. In the end, it makes educated guesses for the blank cells in the table.

In the Classical Multiplicative Time Series Data, to get the Moving Average and Center Moving Average, if the set is an even number: average the data according to the number of the set, then average the Moving Average by 2 to get the Center Moving Average since the Moving Average sets the data below the average rather than at the center of the set. If the set is an odd number, you can average the data according to the number of sets since you can locate the center of the set if the number of sets is an odd number.

In addition, to get the seasonalize component and the irregular component, divide Y_t , the original data, by the Center Moving Average (CMA). Align the results of the S_t and I_t to the result of the Center Moving Average (Wonglimpiyarat, 2017). We need to extract the irregular component because we want to quantify just the seasonal component. For example, if we have 7 days in a week, then we have 7 seasonal components. To get the seasonal component, average all of the days in a week. After getting the average, insert the average in the seasonal component accordingly, meaning only put the average of day 1 in every day 1 of every week (Australian Bureau of Statistics, 2022).

Furthermore, to get the deseasonalized data, divide Y_t by S_t . Because the deseasonalized data extracts the seasonalized and irregular data and because the information is lost during the seasonal adjustment process, one should retain the original data for future modeling purposes.

To get the trend component, the researchers needed to get the Simple Linear Regression using the deseasonalized data as the Y variable and the t, or time code, as the X variable. It is important to do a simple linear regression to get the coefficient of the Y variable and X variable. Calculate the Y variable + X variable x the timecode for that row. To get the forecast data, multiply the seasonal component by the trend component. Forecasting implies going into the future, but what the researchers have done is, based on the data provided, just forecast for periods that already have, which is the actual data or the historical price data. "Forecasting" is more suitable than "Predicting" because prediction (which is highly precise) is essentially impossible, but to a greater or lesser degree, forecastability (less precise but more probabilistic) is applicable to market time-series data.

Data Analysis

The data was analyzed using contextual data analysis, which was based on historical price information, currency demand, currency value, and the coefficient in forecasting the estimated value of the currency at any future date. The researchers used the regression method—Simple Linear Regression—where it will assess the relationship between a dependent variable and an independent variable. The demand function for a product is estimated where demand is a dependent variable and variables that determine the demand are independent variables.

The researchers will also be using time-series analysis, wherein time-series analysis means recording data points at consistent intervals over a set period of time rather than just recording the data points intermittently or randomly. The kind of time series model being used is the Classical Multiplicative Time Series Model where $Y_t = S_t \times I_t \times T_t$.

Ethical Considerations

The researchers are held to high ethical standards by their respondents, ensuring that both the function and the information are not tarnished. The researchers had a responsibility to use the data to enhance social exchange between different sectors. The researchers are held responsible for any mishaps and will not be biased by any of the information given. Furthermore, the researchers protected the participants' anonymity as formal consent is required before the information is revealed. Researchers respect the participants and they should be viewed as respected partners in the research process and as social equals to the researcher.

RESULTS

The Ability of Cryptocurrency to Withstand Inflation

Figure 2

BCoin Historical Price Data and Top Games DAPP Ranked

Figure 2 shows the Historical Price Data of BCoins as it is affected by inflation and Bcoins' popularity as it is ranked as one of the most played crypto games as of November. Based on the results, cryptocurrencies have tracked inflation higher this month due to the increase in players and their growing popularity, thus considering them vulnerable to inflation. However, they can only resist inflation on a small scale.

Figure 6
Forecast Data for January 2022 (Time Series Plot of the Price of BCoins in the Month of December 2021)

The Relationship Between Historical Price Data and Forecast Data

Figure 3 shows an increasing gap between the Historical Price Data and Forecast Data. The forecast data assumed the data to increase in price according to last month's historical data, while the historical data has a decreasing trend in price. Based on the results, it is most likely that there could hardly be any eminent factor between the historical data and forecast data that affects the relationship between the two.

Evaluating Cryptocurrency Through Forecasting

Figures 4 to 6 show the Time Series Plot of Bitcoins for the months of October, November, and December. It could also be seen that the historical data, center moving average, and forecast data are evident in each of the graphs. Based on the results, Figure 4 shows a mixed positive and negative trend for the historical data and CMA, but the forecast data shows a negative trend. On the other hand, Figures 5 and 6 show that all 3 components move in the same direction, following a linear trend, thus showing the possibility of historical data to be a factor that affects the forecast outcome.

DISCUSSION

Nowadays, cryptocurrency is arising in our economy. That is why many companies are creating their own currencies to improve transactions and reduce the hustle that can be used to trade for goods or services. With the sudden growth of cryptocurrency, researchers decided to conduct studies that can help further understand cryptocurrency through different variables of understanding and analysis that can help determine the underlying growth and importance of cryptocurrency. The researchers wanted to provide information that would benefit investors as well as visualize the results, which would aid in further interpreting the data and determining whether it affected the movement or not. The findings confirmed the influence of cryptocurrency on inflation, the similarities and differences between the historical price data and forecast data, and the visualization of the result of the forecasting with the given data.

This research showed a clear understanding of how cryptocurrency works by providing information and visualizing the data through forecasting as it can be considered a prominent study by both researchers and investors due to its important role in the economy. The study aimed to understand cryptocurrency by

analyzing the behavior and movement of the market in order to achieve the best profit margins for investing while avoiding investment risk. As such, this study coincided with the Efficient Market Hypothesis, where it is stated that the market is absolute and projecting the direction of the trend is impossible because of the complex behavior and unstable nature of the market. Furthermore, projection can pose a problem similar to accurate predictions. That is why a forecast suits the study best, as it shows the most likely outcome by making an educated guess with the given data. Similar to the DAVIS framework proposed for a unified solution for data collection, analysis, and visualization in real-time stock market prediction by Tuarob et al. (2021), the results of this study showed consistency as both studies analyzed the behavior of the market and showed results that answered the aforementioned research questions.

In an age where people rely heavily on information and technology (the Digital Generation), it is hard to determine if a piece of information can be trusted or not. Information that can be considered tedious should be discussed and explained properly in order to avoid any misconceptions. As such, the researchers addressed these problems with cryptocurrency in order for them to be knowledgeable when it comes to investing. The results showed a positive outcome that can help develop more contextual knowledge and discover more information about the behavior, nature, and movement of the market when it comes to forecasting. Integrating the forecast and extending it with other financial applications could increase the possibility of the forecast data being directly proportional to the existing ones, which also increases the practicality of this study and the methods used.

CONCLUSION, IMPLICATIONS AND RECOMMENDATIONS

Cryptocurrencies are more likely to be vulnerable to inflation but can only resist inflation on a small scale. There is a low to no possibility of historical price data and forecast contextual data coinciding with one another as the method used is forecasting, where it shows the most likely outcome. The study used a method where one makes an educated guess with the historical price data, as the researchers could not take uncertainty for granted. The data forecasting method is based on historical price data. As such, it is hard to consider the forecast data to be accurate as it is calculated based on the data, which is the certainty and does not include the uncertainty that could affect the movement of the market.

This study is limited by its limitations and restrictions, such as time and the lack of information on financial applications. Due to the limited time presented, the study only used the best possible gathered data to strengthen the credibility of the information. The study needs further research to expand the information, but in order to do that, the researchers need to explore other cryptocurrencies. While the results are answered thoroughly by visualizing the forecast data, there are still ways that can be done in order to improve the research. The researchers believe that this study can be further extended with a wide variety of innovative financial applications if incorporated. Despite an answer provided if cryptocurrency can resist inflation,

with the lack of information and data gathered, it can only be satisfied with a valid answer rather than a satisfactory or factual one.

For a better result, interpretation of data, and clearer understanding of this research study, it is recommended to include other financial applications, which could increase the accuracy of the result, increase the number of cryptocurrencies to be conducted, and conduct questions based on people's perspectives about the credibility of cryptocurrency rather than only focusing on the experiment itself, which could further strengthen the reliability of the data as well as the study itself.
